

## Endpoint Denial of Service: Application or System Exploitation, Sub-technique T1499.004 - Enterprise

Archived: 2026-04-05 14:46:17 UTC

Adversaries may exploit software vulnerabilities that can cause an application or system to crash and deny availability to users. <sup>[1]</sup> Some systems may automatically restart critical applications and services when crashes occur, but they can likely be re-exploited to cause a persistent denial of service (DoS) condition.

Adversaries may exploit known or zero-day vulnerabilities to crash applications and/or systems, which may also lead to dependent applications and/or systems to be in a DoS condition. Crashed or restarted applications or systems may also have other effects such as [Data Destruction](#), [Firmware Corruption](#), [Service Stop](#) etc. which may further cause a DoS condition and deny availability to critical information, applications and/or systems.
