

# grap: Automating QakBot strings decryption

Archived: 2026-04-06 00:28:12 UTC

Published: September 10, 2020

Our [last grap post](#) demonstrated on how to use grap to create and find patterns within QakBot samples.

This post focuses on QakBot's documented strings decryption feature:

- Create patterns to find the function where it is implemented
- Extract relevant variables (decryption key...)
- Automate decryption:
  - within IDA
  - as a standalone script using `pefile` and grap bindings

## 1 - Decryption function

QakBot's strings are encrypted using a simple XOR cipher with a repeating key [2].

Looking into a decryption implementation [2] we find the operation `idx & 0x3F` (the key size is  $0x40=64$ ), let's use grap to find it with IDA bindings ( `opcode is 'and'` and `arg2 is 0x3f` ):

The screenshot displays the IDA Pro interface with several assembly windows and a Python console. The assembly windows show code snippets such as:

```

loc_3941788:
lea    ecx, [eax+edx]
lea    ebx, [edi+ecx]
and    ebx, 3Fh
mov    bl, byte_3952D30[ebx]
xor    bl, [esi+edx]
inc    edx
mov    [ecx], bl
cmp    edx, [ebp+var_4]
jb     short loc_3941788
    
```

The Python console shows the following output:

```

Python>import idagrap
Python>m=pygrap.ida_quick_match("opcode is 'and' and arg2 is 0x3f")
Matched: quick_pattern (4)
quick_pattern, match 1
1: 0x3941680, and ecx, 0x3f

quick_pattern, match 2
1: 0x394178e, and ebx, 0x3f

quick_pattern, match 3
1: 0x3941744, and edx, 0x3f

quick_pattern, match 4
1: 0x3944a4d, and eax, 0x3f
    
```

On the right, a small window shows a control flow graph (CFG) with nodes and edges, highlighting the locations where the search patterns were found.

Two (out of four) matches are in the same function that implements strings decryption. The decryption function takes an offset as argument, decrypts the ciphertext at this offset, and returns the plaintext.

A first pattern to detect this decryption function focuses on the `and` and `xor` operations within a loop (see [qakbot\\_strings\\_3f.grapp](#)):

```

digraph qakbot_strings_3f {
  loop [cond="nfathers==2"]
  any1 [cond=true, repeat=*, lazyrepeat=true]
  and [cond="opcode is 'and' and arg2 is 0x3f"]
  any2 [cond=true, repeat=*, lazyrepeat=true]
  xor [cond="opcode is 'xor'"]
  any3 [cond=true, repeat=*, lazyrepeat=true]

  loop -> any1
  any1 -> and
  and -> any2
  any2 -> xor
  xor -> any3
  any3 -> loop [childnumber=2]
}
    
```

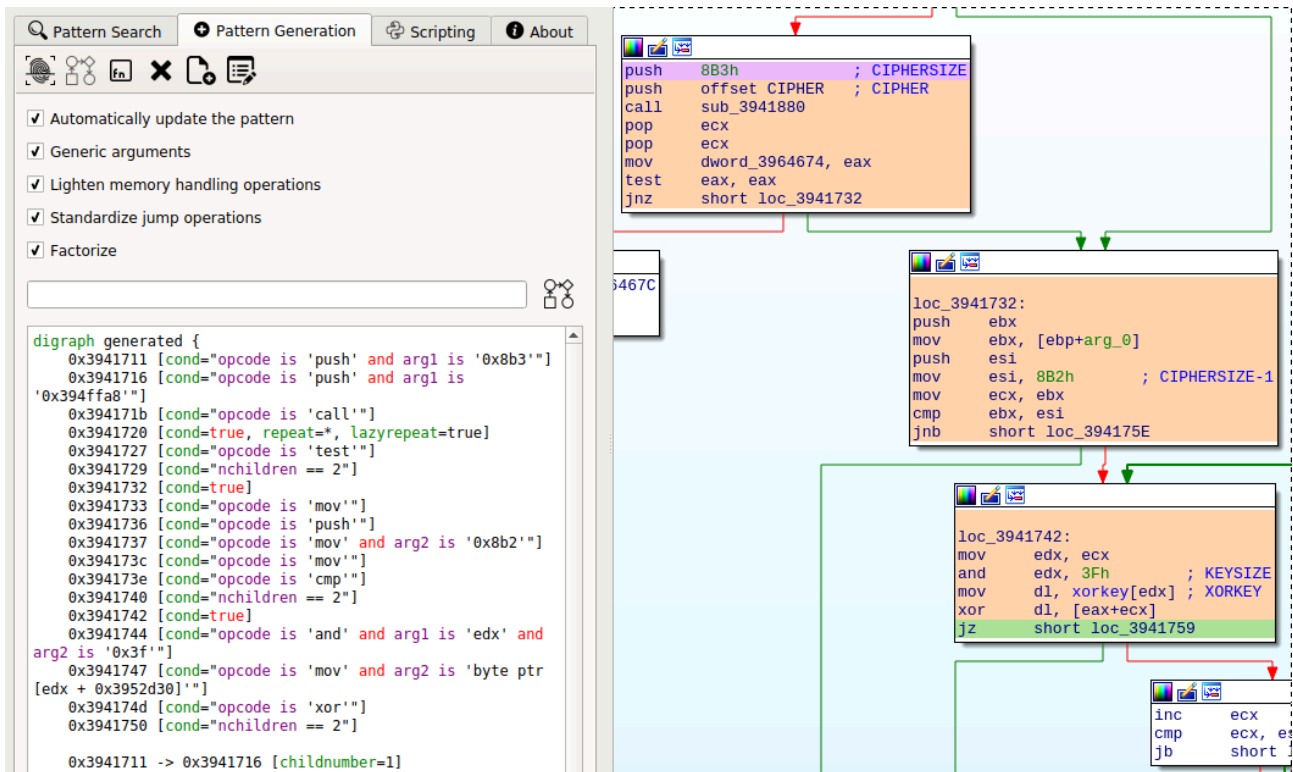

## 2 - Parsing variables

We have found the decryption function, we can use grap to create a more precise pattern. As we want to automate decryption we have to find function variables, including:

- Address and size of the ciphertext
- Address and size of the keystream

## 2.1 - Pattern creation

Let's create an initial pattern with the IDA plugin :

We used the UI to create a pattern matching exactly the instructions containing the variables. Let's edit it to:

- Match when the variables are different (match on opcode for instance)
- Output the instructions where variables are defined with `getid`

The parsing pattern for the decryption function is (see [qakbot\\_strings\\_parsing.grapp](#)):

```
digraph qakbot_strings_parsing {
  0x3941711 [cond="opcode is 'push'", getid=1_CIPHERSIZE1]
  0x3941716 [cond="opcode is 'push'", getid=2_CIPHER]
  0x394171b [cond="opcode is 'call'"]
  0x3941720 [cond=true, repeat=*, lazyrepeat=true]
  0x3941727 [cond="opcode is 'test'"]
  0x3941729 [cond="nchildren == 2"]
  0x3941732 [cond=true]
  0x3941733 [cond="opcode is 'mov'"]
  0x3941736 [cond="opcode is 'push'"]
  0x3941737 [cond="opcode is 'mov'", getid=3_CIPHERSIZE2]
  0x394173c [cond="opcode is 'mov'"]
  0x394173e [cond="opcode is 'cmp'"]
  0x3941740 [cond="nchildren == 2"]
  0x3941742 [cond=true]
  0x3941744 [cond="opcode is 'and'", getid=4_KEYSIZE]
  0x3941747 [cond="opcode is 'mov'", getid=5_XORKEY]
  0x394174d [cond="opcode is 'xor'"]
  0x3941750 [cond="nchildren == 2"]

  0x3941711 -> 0x3941716 [childnumber=1]
  0x3941716 -> 0x394171b [childnumber=1]
  0x394171b -> 0x3941720 [childnumber=1]
  0x3941720 -> 0x3941727 [childnumber=1]
  0x3941727 -> 0x3941729 [childnumber=1]
  0x3941729 -> 0x3941732 [childnumber=2]
  0x3941732 -> 0x3941733 [childnumber=1]
  0x3941733 -> 0x3941736 [childnumber=1]
  0x3941736 -> 0x3941737 [childnumber=1]
  0x3941737 -> 0x394173c [childnumber=1]
  0x394173c -> 0x394173e [childnumber=1]
  0x394173e -> 0x3941740 [childnumber=1]
  0x3941740 -> 0x3941742 [childnumber=1]
  0x3941742 -> 0x3941744 [childnumber=1]
  0x3941744 -> 0x3941747 [childnumber=1]
  0x3941747 -> 0x394174d [childnumber=1]
  0x394174d -> 0x3941750 [childnumber=1]
}
```

## 2.2 - Variables across samples

We can use grep to output matching instructions from samples with the wanted decryption function:

```
$ grap qakbot_strings_parsing.grapp *.grapcfg | grep CIPHERSIZE1
1_CIPHERSIZE1: 0x5f09cb, push 0x8a3
1_CIPHERSIZE1: 0x5f15cb, push 0x8a3
1_CIPHERSIZE1: 0x403537, push 0x1567
1_CIPHERSIZE1: 0x590ccfa, push 0x14d0
1_CIPHERSIZE1: 0x2ff87af, push 0xa8e
```

```
1_CIPHERSIZE1: 0x1cd90a, push 0x14d0  
1_CIPHERSIZE1: 0x2ed238c, push 0xa45  
1_CIPHERSIZE1: 0x7aa7aff, push 0xa8e  
1_CIPHERSIZE1: 0x403537, push 0x1567  
[...]
```

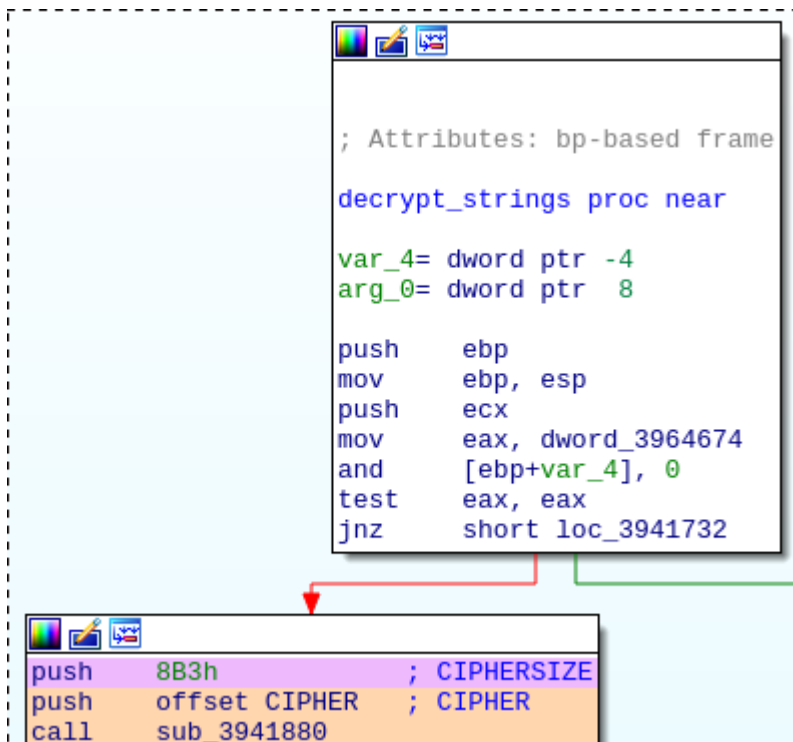

We find that:

- CIPHERSIZE varies across samples
- KEYSIZE is always 0x40

### 3 - Matching the whole function

We want to study calls to the decryption function. For this we need to find its entrypoint.

Back into our sample, the created pattern does not begin at the function entrypoint but there is only one basic block in between:

This basic block can be matched easily:

- Match the first instruction based on multiple incoming nodes (the decryption function is called many times): `nfathers>=5`
- Match the remainder of the basic block with `repeat=* ( lazyrepeat=false )`

This can be included into the previous pattern (see [qakbot\\_strings\\_parsing\\_func.grapp](#)):

```
digraph qakbot_strings_parsing_func {
  EP [cond="nfathers>=5", getid=0_EP]
  BB [cond=true, repeat=*]
  0x3941711 [cond="opcode is 'push'", getid=1_CIPHERSIZE1]
  0x3941716 [cond="opcode is 'push'" getid=2_CIPHER]
```

### 4 - Matching function calls

The decryption function is called with its argument (offset within the ciphertext buffer) pushed on the stack. Most of the time the `push` is immediately followed by the `call` but this is not always the case:

```
push 608h
call decrypt_strings

push 4Eh ; 'N'
mov [ebp+var_4], edi
mov [ebp+var_18], edi
mov [ebp+var_14], edi
mov [ebp+var_10], edi
call decrypt_strings

push 180h
mov [esi+8], eax
call decrypt_strings
push 47h ; 'G'
mov [ebp+lpString2], eax
call decrypt_strings
```

At this point we know the function entrypoint. So instead of extending the same pattern again, we can use a pattern template using a placeholder for the entrypoint (it will have to be replaced by a script):

```
digraph push_call_func {
  push [cond="opcode is push", getid=PUSH]
  notpush [cond="not(opcode is push)", minrepeat=0, maxrepeat=5, lazyrepeat=true]
  call [cond="opcode is call"]
  func [cond="address == FILL_ADDRESS"]

  push -> notpush
  notpush -> call
  call -> func [childnumber=2]
}
```

### 5 - Automate decryption

We now have the necessary patterns to automate strings decryption in an IDA script:

- Find and parse function variables
- Find calls to the decryption function and parse pushed arguments

#### 5.1 - Parsing the function variables

The python bindings give access to the matched instructions through the named defined by `getid` .

Some of the parsed information is structured (opcode, arg1, arg2, address...) but many fields are simply strings (arg1, arg2 for instance) so you will need some parsing to get the right information. The bindings provide a few parsers:

- `parse_first_immediate`: returns the first integer found in an immediate construct ( `0x3f` returns `0x3f`, `43` returns `43`, `0x23+eax` return `None` )
- `parse_first_indirect`: returns the first integer in an indirect construct ( `[0x394173e]` returns `0x394173e`, `[0x394173e+ax]` returns `None` )
- `parse_first_address`: returns the first hex found integer (with `0x`), regardless of the construct ( `0x3f` returns `0x3f`, `0x23+eax` return `0x23`, `[0x394173e+ax]` returns `0x394173e`, `43` returns `None` )
- `parse_int_hex`: converts a string representing an integer ( `0x3f` , `43` ) into its integer counterpart

```
import pygrap

pattern_function = "... " # see qakbot_strings_parsing_func.grapp

def parse_decrypt_function():
    matches = pygrap.ida_match(pattern_function, print_matches=False)
    if "qakbot_strings_parsing_func" in matches:
        for match in matches["qakbot_strings_parsing_func"]:
            func_addr = match["0_EP"][0].info.address
            size1 = pygrap.parse_first_immediate(match["1_CIPHERSIZE1"][0].info.arg1)
            cipher_addr = pygrap.parse_first_immediate(match["2_CIPHER"][0].info.arg1)
            size2 = pygrap.parse_first_immediate(match["3_CIPHERSIZE2"][0].info.arg2)
            xorkey_addr = pygrap.parse_first_address(match["5_XORKEY"][0].info.arg2)

            if size1 != size2 + 1:
                print("ERROR: size1 and size2 do not match")
                return

            print("Decryption function at:", hex(func_addr))
            print("XOR key at:", hex(xorkey_addr))
            print("XOR key:", idc.get_bytes(xorkey_addr, 0x40).hex())
            print("Cipher block at:", hex(cipher_addr))
            print("Cipher block size:", hex(size1))

        return func_addr, xorkey_addr, cipher_addr, size1
```

Ran into IDA, the script parses the decryption function:

```
Decryption function at: 0x3941700
XOR key at: 0x3952d30
XOR key: 3378491dd6630953d76908af270f27b15acbea96d79660cd10625d530e96ab5c153d1630b20b03a5e6e6731dd41318729ab979b1b7d6a01cb95b78447a8b45b9
Cipher block at: 0x394ffa8
Cipher block size: 0x8b3
```

## 5.2 - Decrypting strings

We now have the function variables and can, for each function call, decrypt the corresponding string and add a comment within IDA.

```
pattern_call=""
digraph push_call_func {
```

```
push [cond="opcode is push", getid=PUSH]
notpush [cond="not(opcode is push)", minrepeat=0, maxrepeat=5, lazyrepeat=true]
call [cond="opcode is call"]
func [cond="address == FILL_ADDRESS"]

push -> notpush
notpush -> call
call -> func [childnumber=2]
}
"""

def decrypt_strings():
    func_addr, xorkey_addr, cipher_addr, cipher_size = parse_decrypt_function()

    pattern_call_final = pattern_call.replace("FILL_ADDRESS", hex(func_addr))
    matches = pygrap.ida_match(pattern_call_final, print_matches=False)

    if "push_call_func" in matches:
        for match in matches["push_call_func"]:
            push_inst = match["PUSH"][0]
            push_addr = push_inst.info.address
            offset = pygrap.parse_first_immediate(push_inst.info.arg1)
            if offset:
                dec = decrypt_string(offset, xorkey_addr, cipher_addr, cipher_size)
                print(hex(push_addr), hex(offset), dec)
                idc.set_cmt(push_addr, dec, 1)
```

The decryption itself is a XOR stream cipher:

```
def decrypt_string(offset, xorkey_addr, cipher_addr, cipher_size):
    if offset >= cipher_size:
        return
    res = ""
    while offset < cipher_size - 1:
        cipher_b = idc.get_bytes(cipher_addr+offset, 1)[0]
        key_b = idc.get_bytes(xorkey_addr + (offset&0x3F), 1)[0]
        c = cipher_b ^ key_b
        if c == 0:
            break
        res += chr(c)
        offset += 1
    return res
```

As expected the script appends decrypted strings as a comment:

|   |   |
|---|---|
| <pre> push    ebp mov     ebp, esp sub     esp, 218h push    1BEh ; "%s\system32\schtasks.exe" /create /tn %s /tr "%s" /sc %s call    decrypt_strings push    [ebp+arg_8] mov     [ebp+var_8], eax push    [ebp+arg_4] push    [ebp+arg_0] push    offset Value ; arglist push    eax ; pszFmt </pre> | <pre> mov     ebp, esp push   ecx push   esi push   71h ; 'q' ; c:\pagefile.sys.bak2.txt call   decrypt_strings push   eax mov    [ebp+var_4], eax call   sub_3940A34 mov    esi, eax lea   eax, [ebp+var_4] push  eax </pre> |

```

The full IDA script can found here: [qakbot\\_strings\\_decrypt\\_IDA.py](#)

## 5.3 - Standalone script

The script needs some change for it to run without IDA:

- Replace IDA functions with `pefile` alternatives: `idc.get_bytes` -> `pe.get_data`
- Replace grap IDA helpers with generic bindings: `pygrap.ida_match` -> `pygrap.match_graph`
- Add a few checks to handle errors

Out of IDA grap does the disassembly itself, when possible it will rely on an existing `.grapcfg` file:

```

bin_path = sys.argv[1]
dot_path = sys.argv[1] + ".grapcfg"

# use_existing specifies wether an existing dot file should be used unchanged or overwritten
pygrap.disassemble_file(bin_path=bin_path, dot_path=dot_path, use_existing=True)

data = open(bin_path, "rb").read()
pe = pefile.PE(data=data)
pe_baseaddr = pe.OPTIONAL_HEADER.ImageBase

pe_cfg = pygrap.getGraphFromPath(dot_path)
decrypt_strings(pe, pe_baseaddr, pe_cfg)

```

The full script can found here: [qakbot\\_strings\\_decrypt.py](#)

Running it on all the unpacked samples reveals further IOCs:

```

$ for i in *_unpacked; do python3 qakbot_strings_decrypt.py $i; done
---
Sample: s01_unpacked
Decryption function at: 0x590cce9
XOR key at: 0x5920df0

```

## Conclusion

We demonstrated how to use `grap` (through python bindings and the IDA plugin) to find, detect and parse QakBot's documented string decryption function.

`grap` can be used to automate the parsing of the function's variables and arguments. The bindings were used to find and decrypt the obfuscated strings, either within IDA or as a standalone script using `pefile`.
