Hi

A client of mine got infected by something that looks like the Gomasom ransomware, but the end files are all in \*.tar

Here are 2 zip files, one with crypted files and the other with the same file from and old offline backup.

Any idea how to decrypt this?

hxxp://datatest.simonznet.com/RANSOMWARE/

Thanks

Olivier

There was no instruction for decrypt left on the computer. I wrote to the email using a random email and here is their answer

**Good day**

**Your files were encrypted/locked**

**As evidence can decrypt file 1 to 3 1-30MB**

**The price of the transcripts of all the files on the server: 7 Bitcoin**

**Recommend to solve the problem quickly and not to delay**

**Also give advice on how to protect Your server against threats from the network**

**(Files sql mdf backup decryption strictly after payment)!**

You can submit samples of encrypted files and ransom notes to [ID Ransomware](#) for assistance with identification and confirmation. This is a service that helps identify what ransomware may have encrypted your files and then attempts to direct you to an appropriate support topic where you can seek further assistance. Uploading both encrypted files and ransom notes together provides a more positive match and helps to avoid false detections. If ID Ransomware cannot identify the infection, you can post the **case SHA1** it gives you for [Demonslay335](#) to manually inspect the files.

Samples of any encrypted files, ransom notes or suspicious executables (installer, malicious files, attachments) that you suspect were involved in causing the infection can be submitted [here](#) (<http://www.bleepingcomputer.com/submit-malware.php?channel=168>) with a link to this topic. Doing that will be helpful with analyzing and investigating by our crypto experts.

ID Ransomware cannot identify the ransomware.

SHA1 is fd65d1e0b248c8ec254ab3086f5877ff2065d72a

Sending the files to your second link right now.

Ok.

After our experts examine the files, they will post in this topic if they can assist or need further information.

Interesting, I have not seen a ransomware use ".tar". It isn't a valid Tar archive either. Can you also upload the ransom note to ID Ransomware so I can archive it?

Thanks for the sample mike1. Has any further analysis been done on it already? It crashed on my VM. I see RakhniDecryptor lists it, but it stated unsupported when I selected this user's files.

There is no ransom note anywhere. All we figure out was to try to write to the email Embedded in encrypted files filename.

Tech support at Kaspersky Lab said that can not decrypted.

Hello, can someone help with a decoder? It encrypts all files !\_\_\_\_LIKBEZ77777@GMAIL.COM\_\_\_\_.c400  
Below are links to a virus and a link to the encrypted file.
