EternalPetya - yet another stolen piece in the package? | Malwarebytes Labs

By Malwarebytes Labs

Published: 2017-06-29 · Archived: 2026-04-05 16:37:49 UTC

Since June 27th we have been investigating the outbreak of the new Petya-like malware armed with an infector similar to WannaCry. Since day one, various contradicting theories started popping up. Some believed that this malware is a rip-off of the original Petya, while others think that it is another step in Petya's evolution. However, those were just different opinions and none of them were backed up with enough evidence to hold solid. In this post, we will try to fill this gap by making step-by-step comparisons of the current kernel and the one on which it is based (Goldeneye Petya).

Analyzed sample:

- 71b6a493388e7d0b40c83ce903bc6b04 – the main DLL
  - f3471d609077479891218b0f93a77ceb – the low level part (Petya bootloader + kernel) <- *the main focus of this analysis*

Why is it important to know whether or not the code was recompiled?

Answering this question and collecting enough evidence is crucial for further discussions on attribution. The source code of the original Petya has never been leaked publicly, so in case it was recompiled it proves that the original Petya's author, Janus, is somehow linked to the current outbreak (either this is his work or he has sold the code to another actor).

In this analysis, we hope to identify if this malware could have been recompiled from the original code, or it's just a work of anyone with the appropriate skills to modify the ready-made binary. Doing so would not entirely disprove Janus as the creator, but his involvement becomes less likely.

Anyways, let's take a look at the code.

Sectors

Looking at the sectors, we can find that the layout of EternalPetya is identical to Goldeneye. Full comparison:

Petya kernel:

- Petya Goldeneye: sector 1
- Petya Eternal: sector 1

Data sector:

- Petya Goldeneye: 32

- Petya Eternal: 32

Verification sector:

- Petya Goldeneye: 33
- Petya Eternal: 33

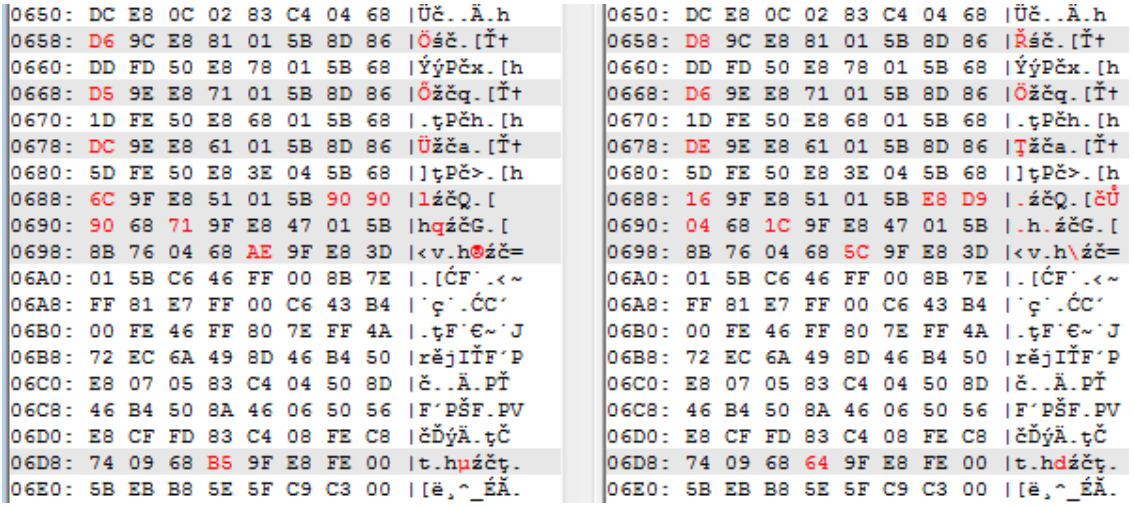
Original MBR (xored with 7)

- Petya Goldeneye: 34
- Petya Eternal: 34

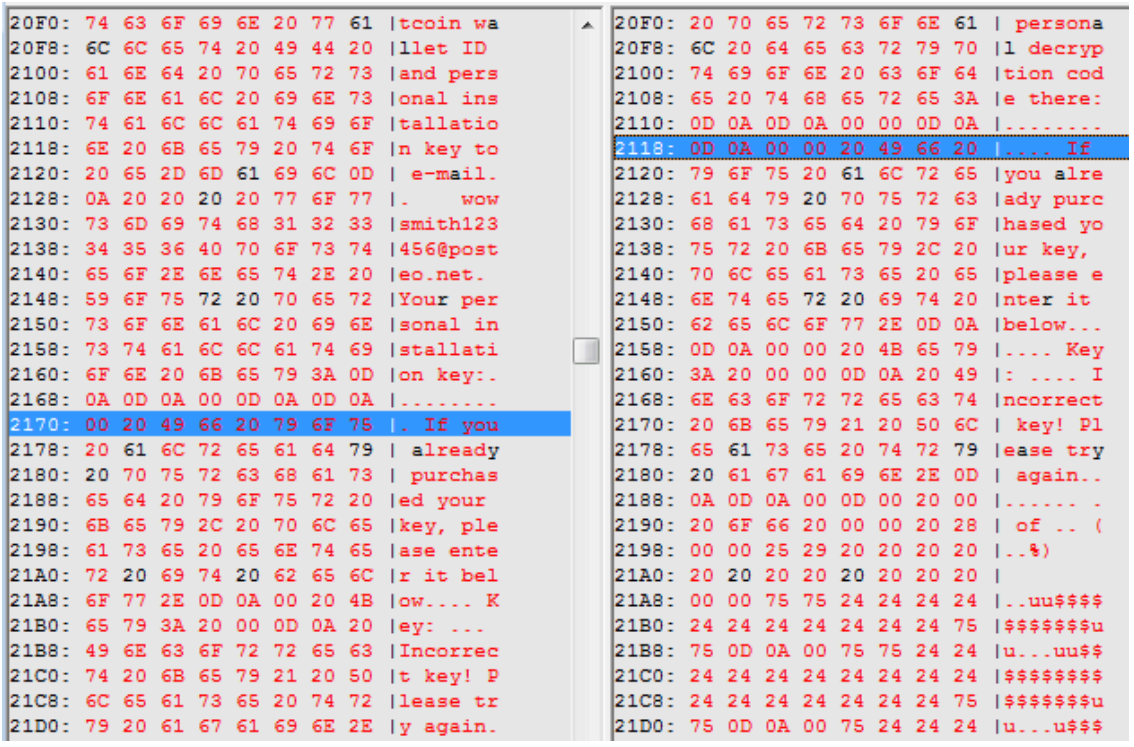
Hexadecimal comparison

Comparing both kernels at hexadecimal level, we can see tiny differences at various points. However, there are big portions of code that are identical in both.

The screenshots below show fragments of the (current) EternalPetya on the left, and Goldeneye on the right.



Its interesting that, at some point, the layout of the same strings in the memory was shifted:



As mentioned, the data sector starts in both cases at the same offset. This sector stores the random Salsa20 key and nonce, which are generated per victim, and this is identical in both cases. However, in Goldeneye the victim ID is much longer, which is not surprising taking into the account the fact that in the past it was supposed to be the encrypted backup of the Salsa key, and now it is just an arbitrary string, so it's length doesn't really matter.

```

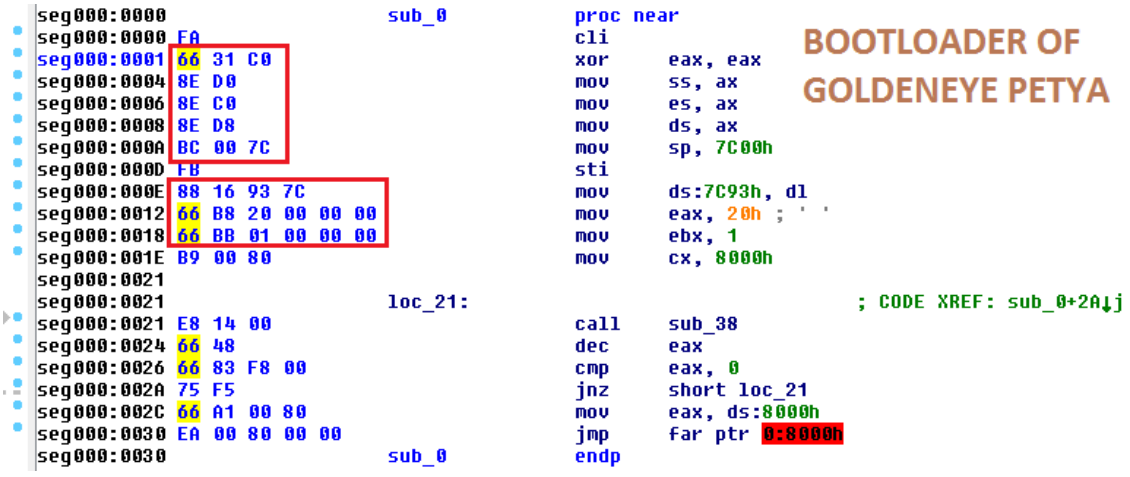
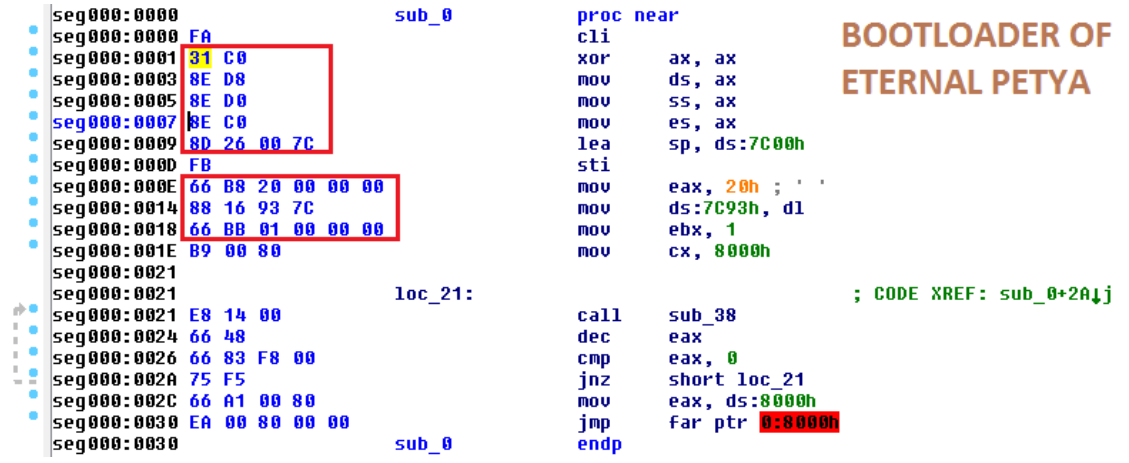
Functionality-wise, it is the same in both cases. It is supposed to read 32 (0x20) sectors from the disk, starting from sector 1, and load them into memory at the address 0x8000. However, the opcodes that are used in both cases to do the same operations are a bit different.

This is the old bootloader, used in Goldeneye:



```
seg000:0000                     sub_0           proc near
seg000:0000 FA                                  cli
seg000:0001 66 31 C0                            xor     eax, eax
seg000:0004 8E D0                               mov     ss, ax
seg000:0006 8E C0                               mov     es, ax
seg000:0008 8E D8                               mov     ds, ax
seg000:000A BC 00 7C                            mov     sp, 7C00h
seg000:000D FB                                  sti
seg000:000E 88 16 93 7C                         mov     ds:7C93h, dl
seg000:0012 66 B8 20 00 00 00                   mov     eax, 20h ; ' '
seg000:0018 66 BB 01 00 00 00                   mov     ebx, 1
seg000:001E B9 00 80                            mov     cx, 8000h
seg000:0021
seg000:0021                     loc_21:                                 ; CODE XREF: sub_0+2A↓j
seg000:0021 E8 14 00                            call    sub_38
seg000:0024 66 48                               dec     eax
seg000:0026 66 83 F8 00                         cmp     eax, 0
seg000:002A 75 F5                               jnz     short loc_21
seg000:002C 66 A1 00 80                         mov     eax, ds:8000h
seg000:0030 EA 00 80 00 00                      jmp     far ptr 0:8000h
seg000:0030                     sub_0           endp
```

And this is the bootloader used in the EternalPetya version:



```
seg000:0000                     sub_0           proc near
seg000:0000 FA                                  cli
seg000:0001 31 C0                               xor     ax, ax
seg000:0003 8E D8                               mov     ds, ax
seg000:0005 8E D0                               mov     ss, ax
seg000:0007 8E C0                               mov     es, ax
seg000:0009 8D 26 00 7C                         lea     sp, ds:7C00h
seg000:000D FB                                  sti
seg000:000E 66 B8 20 00 00 00                   mov     eax, 20h ; ' '
seg000:0014 88 16 93 7C                         mov     ds:7C93h, dl
seg000:0018 66 BB 01 00 00 00                   mov     ebx, 1
seg000:001E B9 00 80                            mov     cx, 8000h
seg000:0021
seg000:0021                     loc_21:                                 ; CODE XREF: sub_0+2A↓j
seg000:0021 E8 14 00                            call    sub_38
seg000:0024 66 48                               dec     eax
seg000:0026 66 83 F8 00                         cmp     eax, 0
seg000:002A 75 F5                               jnz     short loc_21
seg000:002C 66 A1 00 80                         mov     eax, ds:8000h
seg000:0030 EA 00 80 00 00                      jmp     far ptr 0:8000h
seg000:0030                     sub_0           endp
```

My first impression upon seeing this was that the code was recompiled with different settings, however, another possibility also exists. The total length of the different fragments are the same – so, we cannot exclude the possibility that someone manually edited them inside the pre-compiled binary.

Optimizations – and why it matters

So far we've seen some interesting changes, but they were not enough to prove or disprove whether the code was recompiled. However, the breakthrough in the research may lie in the interesting observation made by David Buchanan.

His theory was based on compiler optimization, which ensures that the same character will not need to be loaded into memory twice. We can see this rule applied in examining the code responsible for storing a string in the memory. Inside of Goldeneye's key expansion function, we can find that this kind of optimization absolutely happens – every character is unique, no character is loaded twice:

```
seg000:96D4                     enter   16h, 0
seg000:96D8                     push    di
seg000:96D9                     push    si
seg000:96DA                     mov     [bp+var_11], 'x'
seg000:96DE                     mov     [bp+var_10], 'p'
seg000:96E2                     mov     [bp+var_F], 'a'
seg000:96E6                     mov     [bp+var_E], 'n'
seg000:96EA                     mov     [bp+var_D], 'd'
seg000:96EE                     mov     [bp+var_B], '3'
seg000:96F2                     mov     [bp+var_A], '2'
seg000:96F6                     mov     [bp+var_9], '-'
seg000:96FA                     mov     [bp+var_8], 'b'
seg000:96FE                     mov     [bp+var_7], 'y'
seg000:9702                     mov     [bp+var_6], 't'
seg000:9706                     mov     al, 'e'
seg000:9708                     mov     [bp+var_12], al
seg000:970B                     mov     [bp+var_5], al
seg000:970E                     mov     al, ' '
seg000:9710                     mov     [bp+var_C], al
seg000:9713                     mov     [bp+var_4], al
seg000:9716                     mov     [bp+var_3], 'k'
seg000:971A                     xor     di, di
```

But in the corresponding fragment of the current kernel, we can find that this rule is broken. The character ‘d’ repeats and optimization was not applied:

```
seg000:96D4                     enter   16h, 0
seg000:96D8                     push    di
seg000:96D9                     push    si
seg000:96DA                     mov     [bp+var_11], '1' ; -1nvald s3ct-id
seg000:96DE                     mov     [bp+var_10], 'n'
seg000:96E2                     mov     [bp+var_F], 'v'
seg000:96E6                     mov     [bp+var_E], 'a'
seg000:96EA                     mov     [bp+var_D], 'l'
seg000:96EE                     mov     [bp+var_B], 'd'
seg000:96F2                     mov     [bp+var_A], ' '
seg000:96F6                     mov     [bp+var_9], 's'
seg000:96FA                     mov     [bp+var_8], '3'
seg000:96FE                     mov     [bp+var_7], 'c'
seg000:9702                     mov     [bp+var_6], 't'
seg000:9706                     mov     al, '-'
seg000:9708                     mov     [bp+var_12], al
seg000:970B                     mov     [bp+var_5], al
seg000:970E                     mov     al, 'i'
seg000:9710                     mov     [bp+var_C], al
seg000:9713                     mov     [bp+var_4], al
seg000:9716                     mov     [bp+var_3], 'd'
seg000:971A                     xor     di, di
```

If the same code was generated by a compiler, this fragment would look identical to other repeated characters:

```
mov al, 'd' mov [bp+var_B], al mov [bp+var_3], al
```

This is a very strong argument against the theory of the code being recompiled. But anyway, let’s continue the analysis and see if we can find even more evidence.

Closer look at the changes

In a previous post I presented a fast comparison of the current kernel vs Goldeneye, done with the help of IDA plugin, BinDiff:

similarity	confide	change	EA primary	name primary	EA secondary
1.00	0.99	-------	000088C4	sub_88C4_13	000888C4

1.00	0.88	-------	00009518	sub_9518_29	00089518
1.00	0.88	-------	00009578	sub_9578_30	00089578
0.99	0.99	-I--E--	00008426	main_info_screen	00088426
0.16	0.38	GI--EL-	000086E0	sub_86E0_11	000886E0

We can see that significant modifications have been made only in the functions related to displaying the information screen. Let’s check how exactly these changes have been applied.

main_info_screen (offset 0x8426):

Changes of the main_info_screen pointed out by the BinDiff (left: current, right: Goldeneye):

```
00008487   push    b2 0xFFFF9F6C
0000848A   call    b2 display_string
0000848D   pop     b2 bx
0000848E   nop
0000848F   nop
00008490   nop

00008491   push    b2 0xFFFF9F71
00008494   call    b2 display string
```

```
00088487   push    b2 0xFFFF9F16
0008848A   call    b2 0x85DE
0008848D   pop     b2 bx

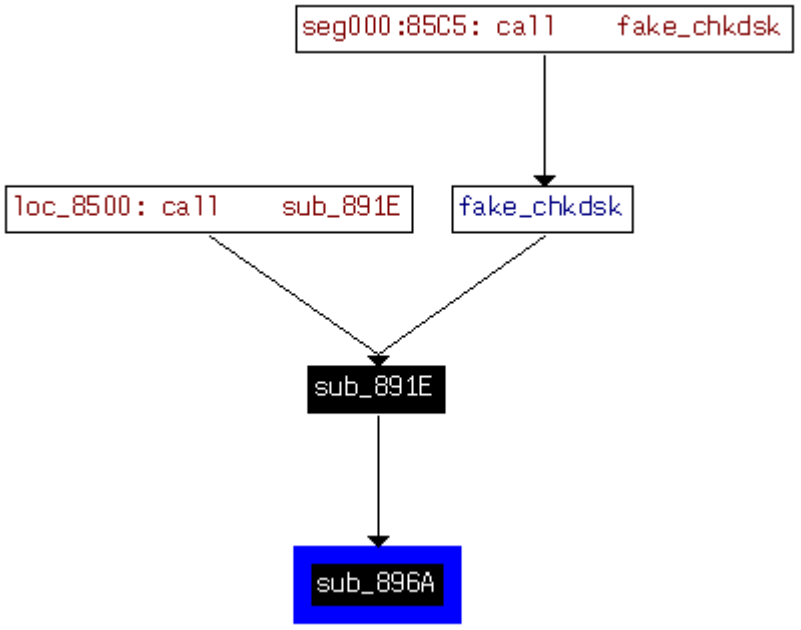
0008848E   call    b2 0x896A
00088491   push    b2 0xFFFF9F1C
00088494   call    b2 0x85DE
```

As we can see, the call to a function at 0x008848E was replaced with NOPs (No Operation). This is a common practice used to remove an unwanted function in case of patching compiled binaries. Yet, sometimes it can be also introduced by #Ifdefs. The rest of the code matches the previous version, even using the same offsets. However, the addresses to the displayed strings are different in both binaries.

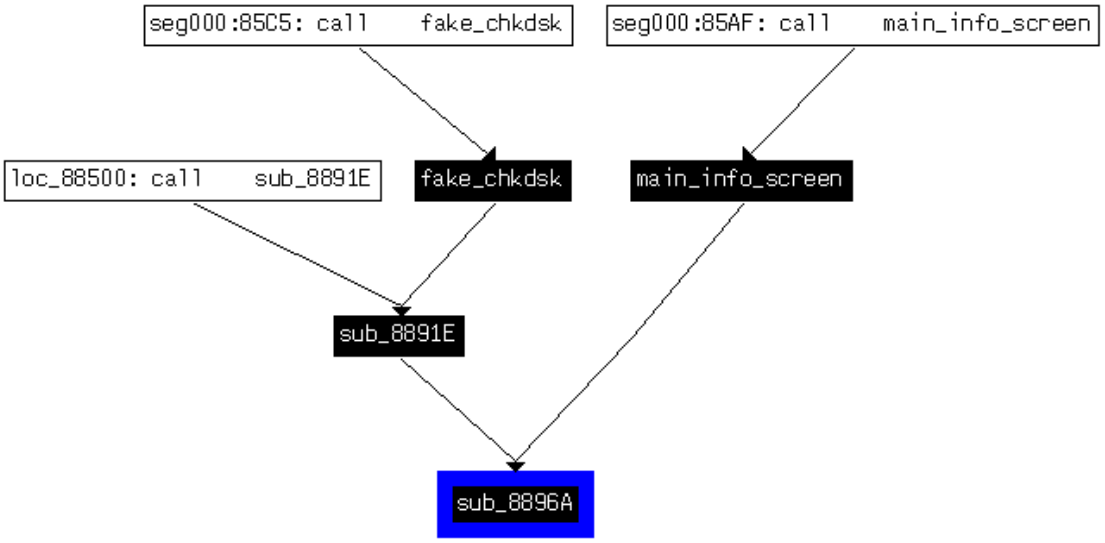
The unreferenced function is still present in the current binary:

```
seg000:896A
seg000:896A                 sub_896A        proc near
seg000:896A 6A 00                           push    0
seg000:896C E8 03 00                        call    read_key
seg000:896F 5B                              pop     bx
seg000:8970 C3                              retn
seg000:8970                 sub_896A        endp
```

…and called in some other places of code:

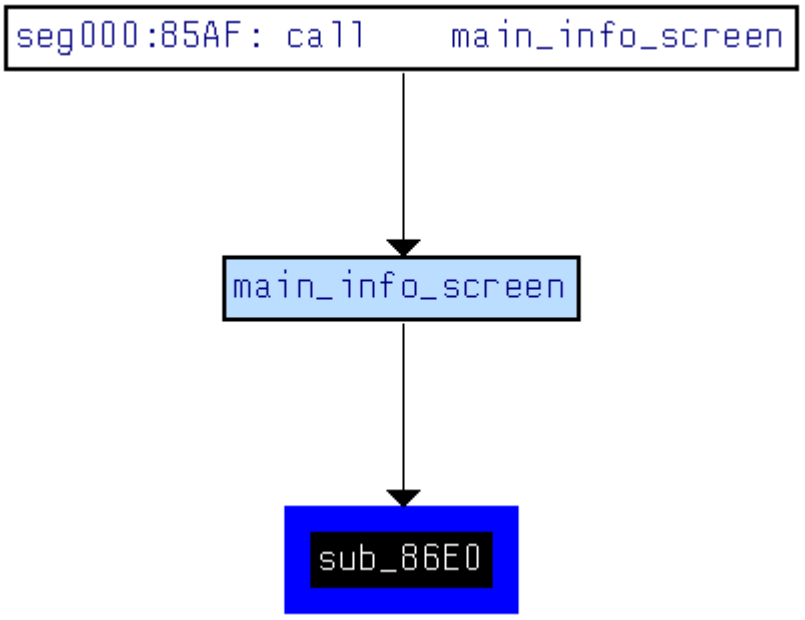


Comparison to the Goldeneye's call graph, it lacks one of the references, but the other ones are consistent:



sub_86E0 (offset 0x86E0):

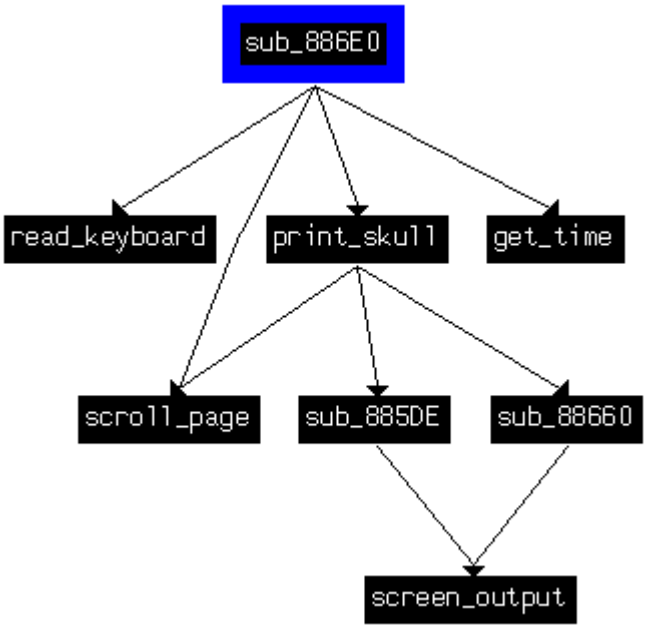
The second change is in another function, that is also a part of the information screen. It is not referenced from any other place in the code:



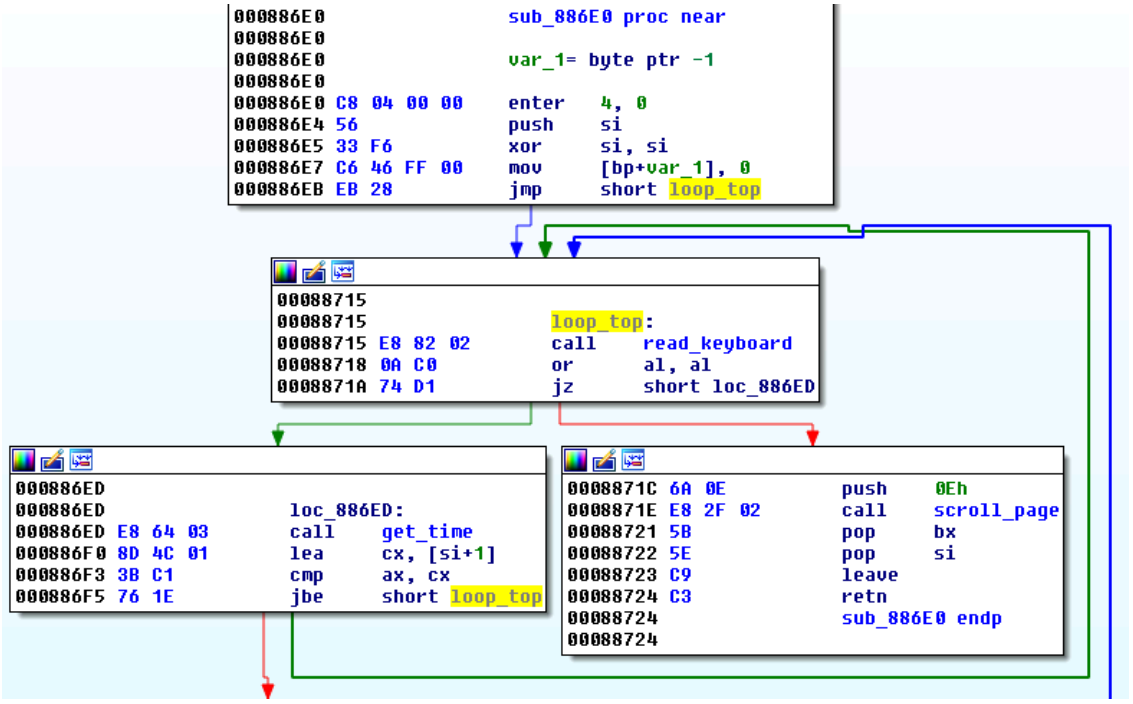
As we can see, it is called at the beginning of the previously discussed function:

```
seg000:8426                main_info_screen proc near
seg000:8426
seg000:8426                var_24C         = byte ptr -24Ch
seg000:8426                var_223         = byte ptr -223h
seg000:8426                var_1E3         = byte ptr -1E3h
seg000:8426                var_1A3         = byte ptr -1A3h
seg000:8426                var_4C          = byte ptr -4Ch
seg000:8426                var_1           = byte ptr -1
seg000:8426                arg_0           = word ptr  4
seg000:8426                arg_2           = byte ptr  6
seg000:8426
seg000:8426 C8 4C 02 00                    enter   24Ch, 0
seg000:842A 57                             push    di
seg000:842B 56                             push    si
seg000:842C E8 B1 02                       call    sub_86E0
```

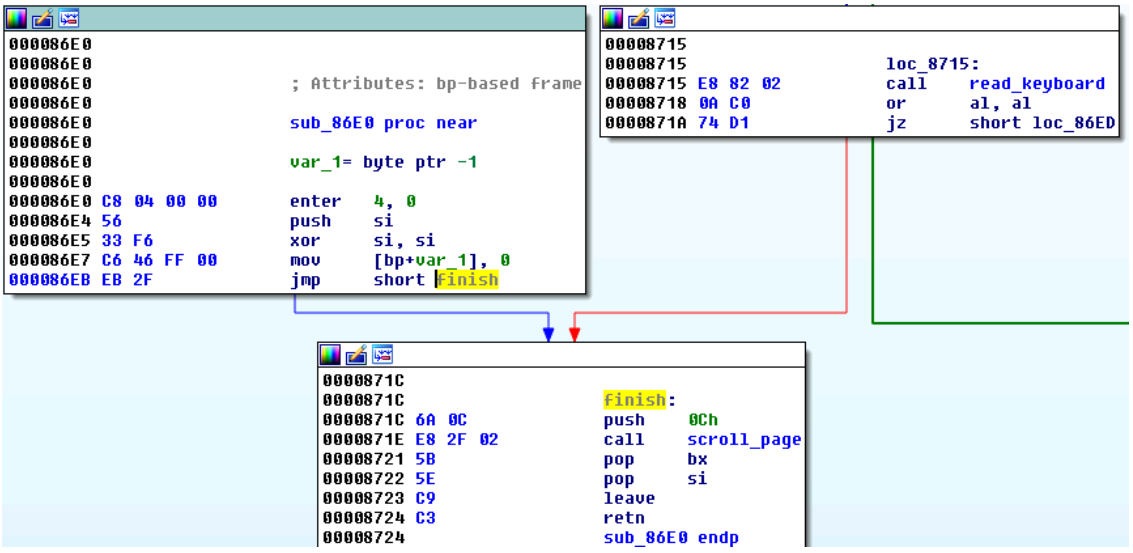
In the Goldeneye kernel, the corresponding function was the one responsible for printing the skull:



The first jump leads to the loop responsible for displaying the skull and waiting for the key to be pressed by the user. Fragment of the code:



Looking inside the EternalPetya code, we are almost sure that this function was patched post-compilation, rather than recompiled. The first jump, that was supposed to lead to the loop leads directly to the function end:



The original code is still in the binary, but it is never referenced (dead code).

Are the patches reversible?

I thought as a finishing touch of this research it would be interesting to reverse the changes and bring the dead code back to life. As an input, I used the dumped code of:

- EternalPetya kernel + bootloader (f3471d609077479891218b0f93a77ceb).

My version (reverse patch): (7957520271edf003742db63fc250c231).

Indeed, after applying the patches, we are back to seeing the same blinking screen, only the skull is gone (the corresponding strings has been overwritten):

Conclusions

I think the presented evidence is enough to prove, that the code was not recompiled from the original source (in contrary to what I initially suspected). Thus, the involvement of the original Petya author, Janus, seems unlikely. It seems in this case he was just chosen as a scapegoat by some different actor.

The edits made in the code are well crafted – the person doing them was fluent in assembly and knew exactly what to change and why. Thus, it gave the first impression of very neat and clean modifications, that could possibly be a result of code recompilation. Yet, after doing a deeper analysis, we have identified numerous nuances that show otherwise.

EternalPetya seems to be a patchwork made of code stolen from various sources. In addition to the modified version of the GoldenEye Petya kernel, we can find the leaked NSA exploits from the “Eternal” series as well as legitimate applications, such as PsExec.

It is common practice among unsophisticated actors (script-kiddies) to steal and repurpose someone else’s code. However, in this case, the composition was done well by a person or team with good technical knowledge and careful execution. A possible reason for using so many stolen elements, apart from saving actor’s time, could have been to throw off any obvious signs of attribution.

There are still many mysteries to solve about this malware which creates many theories that, until proven true, are nothing more than speculation.
